PREFACE

National Residue Program

The Food Safety and Inspection Service (FSIS) of the U.S. Department of Agriculture (USDA) as part of its National Residue Program collects samples of meat and poultry at slaughtering establishments under its inspection authority and from import shipments at the ports of entry. The samples are analyzed for the presence of unacceptable residue concentrations of pesticides, animal drugs, and other potentially hazardous chemicals that may contaminate meat and poultry. These activities are carried out as part of the Agency's responsibilities under the Federal Meat Inspection Act and the Poultry Products Inspection Act to ensure that USDA-inspected products in commerce are safe, wholesome, and free of adulterating residues.

Purpose of Document

This document--now in its eighth edition--details the activities of the Food Safety and Inspection Service (FSIS) in its evaluation of compounds that may be present in meat and poultry and its development and implementation of analytical methods for detecting those compounds; it includes the National Residue Program Plan. The document serves as a reference source for those concerned with food safety and with FSIS activities in that area.

Section 1

Section 1 includes "Criteria for Compound Evaluation," which describes the procedure followed by FSIS in evaluating compounds for inclusion in the National Residue Program, and the "List of Compounds Considered." The list was compiled by reference to the separate entries in the Code of Federal Regulations (CFR) and the New Animal Drug Application (NADA) listing of the Food and Drug Administration. The list provides the compound name and appropriate CFR or NADA references. NADA references are used for approved animal drugs not listed in the CFR. The third column indicates the "residue designation" used by the National Residue Program to denote the compounds or compound classes comprised by the Program. The fourth column gives the ranking assigned to the compound in the National Residue Program. The fifth column indicates the compounds included in the National Residue Program during a ten-year period and the specific years in which a compound was included; this column replaces the historical section of previous editions.

Section 2

Section 2 is a list of tolerances and action levels for the compounds.

Section 3

Section 3 defines the types of methods used by FSIS to conduct analyses and their suitability for regulatory use; defines key terms used to describe the methods; and lists the analytical methods for compounds in alphabetical order.

Section 4

Section 4 is the National Residue Program Plan for the calendar year 1991, which describes domestic and import program activities. The plan is a guide based on current information, assessment of precedence for testing, and FSIS analytical capability. It is dependent upon our having full staffing and is therefore affected by loss of personnel. The plan will be modified during the year as new information alters the original assessment.

Address for Comments

Section 1

CRITERIA FOR COMPOUND EVALUATION AND RANKING

Introduction

Livestock and poultry may be exposed to many compounds during their life cycle. These compounds include primarily:

Pesticide chemicals approved for direct application to livestock and poultry or for treating crops that become components of animal feed or that are used in some way in the farm environment

Animal drugs used to treat or prevent disease or otherwise enhance production

Environmental contaminants

The Environmental Protection Agency (EPA) and the Food and Drug Administration (FDA) establish the acceptable levels or limits of residues (tolerances or action levels) for these compounds in their respective areas of responsibility (pesticides, EPA; animal drugs, environmental contaminants, FDA) and the approved methods of use for specific crops or animals that ensure that limits will not be exceeded. If limits are not established for unavoidable contaminants, FSIS may request that FDA recommend action levels. Exposure of animals to environmental contaminants, or the use of pesticides or animal drugs in a way that does not conform with approved uses, can result in unacceptable amounts of residues of these chemicals in the edible tissues of animals at slaughter.

CFR References

Tolerances for these chemicals are listed in the Code of Federal Regulations (CFR) in 40 CFR 180 for pesticides, in 21 CFR 556 for animal drugs, and 21 CFR 109 for unavoidable contaminants. The approved use conditions for animal drugs are given in 21 CFR in parts 520, 522, 524, 526, 529 (new animal drugs not subject to certification), 540, 544, 546, 548 (antibiotic drugs for animal use), and 558 (new animal drugs for use in animal feed).

Need for Criteria

It is not feasible to monitor for residues of all of these chemicals in meat and poultry, nor is this necessary to adequately protect public health. It is, however, important to assess the likelihood that animals exposed to these chemicals may contain residues at levels of concern, and to conduct monitoring, when test methods are available, for those chemicals that are most likely to present the greatest potential risk. A hierarchical compound-assessment scheme is used for this purpose.

Compound Evaluation System (CES)

In the 1985 edition of this document, FSIS-Science (now Science and Technology) announced the implementation of a new Compound Evaluation System (CES). The CES was designed to provide the agency with a more systematic approach to the categorization of compounds with respect to their likelihood of occurrence in meat and poultry and their potential impact on public health. The CES was subjected to extensive external review by the tri-agency advisory board cited above (Surveillance Advisory Team) and was published. Briefly, the CES addresses the risk of residues in meat and poultry as a function of three major elements: whether a compound will leave a residue, and if so: hazard (adverse effects that may be produced by a given compound) and exposure (residue concentration; factors affecting concentration, such as use patterns, withdrawal times, etc.; duration of or frequency of consumption of product containing residues of concern). Compounds are ranked in a scheme that classifies a given pesticide, animal drug, or contaminant in any one of 24 categories. Compounds of greatest concern carry a designation of A-1 (high health hazard potential; high likelihood of residue occurrence); those compounds of least concern are designated D-4 (negligible health hazard potential; negligible likelihood of residue occurrence). The letter Z is used to indicate an element of the two-value system lacking the information needed for classification. Care is taken to avoid the use of exact numerical rankings that might suggest a high degree of sophistication possibly not justifiable because of data limitations or the assumptions inherent in the ranking process.

CRITERIA FOR COMPOUND EVALUATION AND RANKING

The assignment of a specific ranking is based on a review of information entered in a comprehensive set of CES worksheets prepared for each compound evaluated. These worksheets provide a permanent record and chronology of the nature and extent of the technical and scientific data that were considered. Certain compounds considered within the FSIS National Residue Program have been evaluated using the CES. It should be understood that the rankings are based strictly on data available to FSIS at the time and may well change as additional information becomes available in the open literature, from other agencies, or from the private sector. To further advance the CES effort, FSIS is using outside assistance in the preparation of a series of compound evaluation reports that will provide the basic information necessary to prepare the CES worksheets. To this end, a contract was awarded that calls for the preparation of evaluative reports on 50 compounds of potential concern to the agency. This work is now under way.

FSIS believes that the Compound Evaluation System is sufficiently flexible to permit rapid response to new information that may affect previous rankings and to allow for the use of scientific or expert judgement. It must be emphasized, however, that the CES was neither designed nor intended for use in the development of formal quantitative estimates of risk from meatborne residues. Rather, it provides a rational basis for changes in compound emphasis within the National Residue Program and encourages development of analytical methods for important compounds for which no methods exist. As such, the CES serves as a useful guide in the planning and allocation of FSIS Program resources for those residues considered to represent the greatest potential effect on public health. The CES is updated as appropriate to provide the FSIS with a constant, informative, and sound approach to dealing with residues in meat and poultry. Given the Program's experience with the CES, it has been decided to eliminate the old A-B-C-D rankings; compounds that are not ranked under the CES are marked 'NR' for Not Ranked. The compounds in the List of Compounds Considered that have been assigned values in the CES are listed separately at the end of Section 1.B.

FSIS welcomes comments or suggestions regarding the CES; a copy of the CES document is available upon request. Send comments or requests regarding the CES to:

Selection of Compounds for Monitoring

Compounds are selected for monitoring and included in a plan for the calendar year based on several factors, including:

Compound ranking assigned

Whether a practical test method is available and is suitable for regulatory use

Whether the compound is measurable in a multi-residue method with which many compounds, even though all may not be assigned a high ranking, can be tested for at a relatively low cost

Monitoring or other experience that shows whether adulterating residues are present in meat and poultry

Not all of the hundreds of animal drugs and pesticides listed in the CFR are likely to expose animals to harmful residues. FSIS works from a list of about 400 compounds that includes certain environmental contaminants in addition to animal drugs and pesticides (Section 1.B). Some compounds are routinely included in monitoring because experience shows that without active enforcement adulterating residues will occur. Other compounds may be included in monitoring on a cyclical basis to confirm periodically that a potential residue problem does not exist. Cycling of compounds in monitoring allows the agency to include more compounds in the program than would otherwise be possible within its resources. Compounds rotated out of the program for a specific year are not disregarded; if the need arises, they can be added during that year. Over the last

CRITERIA FOR COMPOUND EVALUATION AND RANKING

ten years, virtually all the residues for which a suitable method was available have been monitored, except when a compound had an especially low rank.

In 1990 FSIS planned to conduct 92,629 sample unit analyses for 19 residue designations (denoting a compound or class of compounds); in 1991 FSIS plans to conduct 100,055 sample unit analyses for 13 residue designations. Table VI in Section 5 of this document shows the resource expenditure required by the sampling plan.

A Dynamic System

The process of compound evaluation and ranking is a dynamic one. Additional compounds have to be considered in the system, agricultural use practices change, and additional research on a compound's toxicity and its potential for leaving harmful residues may affect previous rankings. The agency uses an advisory board of scientists from EPA, FDA, and USDA (FSIS and the Agricultural Marketing Service) to identify significant new information that may affect a compound or ranking or indicate an urgent need for monitoring. This advisory relationship is defined in the Memorandum of Understanding among the three agencies published in the Federal Register on January 16, 1985.

LIST OF COMPOUNDS CONSIDERED

System of Compound Listing and Counting

CFR reference names, when available, are used for the primary entries; common names are given in square brackets, where applicable.

Isomers of a compound--compounds having the same percentage composition and molecular weight but differing in chemical or physical properties--are not listed separately.

Metabolites are listed in this edition with the parent compound.

Complex mixtures such as PCB's are listed as a single entry.

Residue designations denote the compound or compound class names used to compose the annual plan and under which residue results are reported.

In NRP Monitoring Plan provides the historical information given in the Section 4 of previous editions.

Section 2

1991 RESIDUE LIMITS

Introduction

This section provides information on residue limits in meat and poultry products applied by FSIS (as of July 1, 1990). These limits include tolerances and action levels developed by the Environmental Protection Agency (EPA) for pesticide chemicals, and by the Food and Drug Administration (FDA) for animal drugs and unavoidable contaminants. These limits are derived in most cases from the Code of Federal Regulations (CFR): pesticide limits from 40 CFR 180, those for animal drugs from 21 CFR 556, and unavoidable contaminants from 21 CFR 109. The approved use conditions for animal drugs can be found in 21 CFR 520, 522, 524, 526, 529 (new animal drugs not subject to certification), 540, 544, 546, 548 (antibiotic drugs for use with animals), and 558 (new animal drugs for use in animal feed). See Section 1.B of this document for relevant citations.

Formal tolerances are not established in all cases. For example, tolerance exemptions have been granted by FDA and EPA in approving the use of some pesticides and new animal drugs. For some unavoidable contamination situations, FDA and EPA, upon request, recommend action levels to FSIS; however, tolerances or action levels have not been established for all such situations. FSIS permits concentrations of residues in meat and poultry that do not exceed the residue limits published in this section.

The residue limits for poultry and livestock species are listed alphabetically by compound (which may include a compound's metabolites). The entries include, among other things, CFR or Federal Register (FR) citations for tolerances, and notations of action levels. Entries for animal drugs with "zero" or "no residue" tolerances also include, in parenthesis, the limits of quantification considered by FDA in approving uses of those drugs in food-producing animals. These limits are used by FDA for enforcement purposes, and are applied by FSIS in determining if product is adulterated.

Any residue of a new animal drug found in the edible tissues of a species for which the drug is not approved will be considered an adulterant, provided the residue is found at a concentration that can be quantified and confirmed by a validated analytical method. A concentration of a substance endogenous in the animal tissue in question would not be considered an adulterant.

Unless otherwise indicated, "meat byproducts" includes kidney and liver.

Section 3

FSIS RESIDUE ANALYTICAL CAPABILITY

Introduction

The Food Safety and Inspection Service (FSIS) requires practical analytical methods for detecting, quantifying, and identifying all residues that may be present in meat, poultry, and their processed products at levels above established safe residue limits. These methods can be used by the Agency for monitoring and surveillance activities to determine whether product is adulterated. The Agency uses available methodology to take appropriate regulatory action against adulterated products, consistent with the reliability of the analytical data. However, because of the large number of potential residues that may occur in the food chain, practical methods are not available for many compounds of interest. This section describes the types of methods used by FSIS to conduct analyses and their suitability for regulatory use. A list of key terms precedes the method descriptions.

Method Levels

Methods are described in terms of levels of use:

Level I--These are assays with the highest level of credibility. They are unequivocal at the level of interest. They may be single procedures that determine both the concentration and the identity of the analyte, or combinations of determinative methods for concentration and confirmatory methods for definitive identification.

Level II--These are assays that are not unequivocal but are used to determine the concentration of an analyte at the level of interest and to provide some structural information. These methods are reliable enough to be used as reference methods.

Level III--These are screening methods that may generate limited though useful information. These tests detect the presence or absence of a compound or a class of compounds at some concentration level of interest. They are used because of a greater throughput, portability, or convenience than the Level I or Level II methods. The level of reliability has been determined and documented. The hallmark of Level III tests is that action based on individual positive results requires substantiation based on Level I or Level II methods, as required by the uncertainty of any individual results.

Methods are further classified according to their status. Within each classification, subgroups are defined according to the extent to which a method was subjected to study. Therefore, whether (or how well) a specific analytical method meets a defined suitability criterion determines its classification and subgroup.

Criteria for Practical Methods

The following criteria have been identified as guidelines for methods suitable for regulatory use.

1. The method requires no more than 2-4 hours of analytical time per sample.
2. The method requires no instrumentation not customarily available in a laboratory devoted to trace drug or environmental analysis.
3. Chemical methods have a Minimum Proficiency Level (MPL) at or below the established residue limit and antimicrobial methods have a Minimum Inhibitory Concentration (MIC) at or below the established residue limit.
4. A quality assurance plan (QAP) has been developed for the method.

FSIS RESIDUE ANALYTICAL CAPABILITY

5. The method has been subjected successfully to an interlaboratory study at 0, 1/2 X, X, and 2X, where X is the analyte concentration at the residue limit. FSIS considers the methods described for "zero tolerance" compounds to be suitable for regulatory use if they meet the suitability criteria listed above and have an MPL or MIC at the operational definition of zero defined by FDA or EPA. Methods determined to be suitable for regulatory use except for criterion 3 or 5 will be marked with an asterisk (*). In an emergency situation, exceptions to a method's suitability may be necessary.

Method Status

The method status classifications are:

A. AOAC Official Methods. Such methods have been subjected to an interlaboratory study in which five or more laboratories participated. If this collaborative process provides results that establish acceptability, the methods are accepted as official methods by the AOAC. Some AOAC official methods have been subsequently studied for extension as follows:

1. Extension to other analytes, tissues, species, and products by a three-analyst (two or three laboratory) study--a validation study.
2. Extension by a one or two analyst intralaboratory or interlaboratory study as follows:
 - a. Extended to other tissues, species, and products for the initial analyte(s) studied.
 - b. Extended to other similar analytes in the same matrices as initially studied.

B. Validated Methods. Methods subjected to an interlaboratory study in two or three laboratories with a minimum of three independent analysts. The resulting data are reviewed by a peer group of government scientists. The data that result from the study are made available for review upon request. Included in this category would be post-1973 New Animal Drug Application (NADA) methods developed by sponsors that have been successfully studied by FSIS and FDA laboratories. Some validated methods have been subsequently studied for extension by a single or two analyst intralaboratory or interlaboratory study as follows:

1. Extended to other tissues, species, and products for the initial analyte(s) studied.
2. Extended to other similar analytes for the initial tissues/species and products studied.

C. Federal Register Methods. Methods of analysis published in the Federal Register and later incorporated into the Code of Federal Regulations.

D. Historical Official Methods. Methods that were considered to be the best available at the time of initial acceptance and have continued in use over an extended period in the absence of a more effective method. Included in this category would be pre-1974 NADA methods that were submitted by sponsors and accepted by FDA and FSIS without a multilaboratory study.

E. Nonvalidated Methods (NVM). Methods for quantification and/or confirmation that have not been subjected to a multilaboratory study of at least three independent analysts; or, analytical methods that have been subjected to a multilaboratory study but do not meet either criterion 3 or 5 of the criteria for methods suitable for routine use.

FSIS RESIDUE ANALYTICAL CAPABILITY

F. Published Methods. These methods have been subjected to a study by a single analyst or laboratory when the data for evaluation are limited. However, a quality control plan will be in place. The results are reviewed by a peer group of government scientists.

G. Correlated Methods. These methods have not been validated by traditional interlaboratory study, but data obtained from use of the method have been correlated and/or compared with data obtained from use of a method for regulatory enforcement. The same samples must be used for this comparison, and the data must be reviewed by a peer group of government scientists.

FSIS RESIDUE ANALYTICAL CAPABILITY

KEY TERMS

AAS -- Atomic absorption spectrometry

AOAC -- Association of Official Analytical Chemists

CELIA CA -- Competitive Enzyme Labeled Immunoassay for Chloramphenicol: a laboratory test that detects and identifies chloramphenicol residues in cattle and pork muscle

EC -- Electron capture

EI -- Electron impact

E-Z Screen -- A proprietary immunoassay system for rapidly detecting and identifying various antibiotics and other residues in tissue extracts

GC -- Gas chromatography

GLC -- Gas liquid chromatography

GPC -- Gel permeation chromatography

HFB -- heptafluorobutyl[imidazole]

HPLC -- High pressure liquid chromatography

JAOAC -- Journal of the Association of Official Analytical Chemists

J. Food Prot. -- Journal of Food Protection

LDL -- Lowest detectable limit: the smallest amount of individual residue or sample component that can be reliably observed or found in the sample matrix by the current appropriate methodology

Method Status -- See discussion above

MIC -- Minimum inhibitory concentration: the minimum level of antimicrobial compound present in a buffer extract of tissue that will inhibit bacterial growth

MPL -- Minimum proficiency level: the minimum amount of analyte expected to be identified and quantified by a laboratory and upon which ongoing capability will be evaluated. It is the smallest concentration for which the predicted coefficient of variation for reproducibility (CV) is less than or equal to 20 percent and the upper 90 percent confidence level for the predicted CV is less than 30 percent.

MS -- Mass spectrometry

NADA -- New Animal Drug Application, issued by the Food and Drug Administration (FDA)

NE -- Level not established

FSIS RESIDUE ANALYTICAL CAPABILITY

KEY TERMS

NICI -- Negative ion chemical ionization

PCI -- Positive ion chemical ionization

PP -- Processed product

Quantification -- The determination of the amount of residue present in a sample

Reference Methods -- Analytical procedures by which other methods may be evaluated and for which performance standards are established. These methods are considered suitable for regulatory use in the National Residue Monitoring Program.

Residue -- Any compound present in edible tissues of the target animal that results from that compound's use or inadvertent introduction into the animal. "Residue" includes the compound itself, its metabolites, and other substances formed in or on food because of the compound's use or inadvertent introduction.

SOS -- Sulfa-on-Site: a rapid in-plant chemical screening test for detecting sulfonamide residues in food animal urine or serum that provides same-day results

STOP -- Swab Test on Premises: an overnight in-plant microbiological screen test for detecting antibiotic residues in edible tissues

Swab -- STOP precursor: an overnight laboratory microbiological screen test for detecting antibiotic residues in edible tissues

TLC -- Thin layer chromatography

UV -- Ultraviolet spectrophotometric technique for detection and quantification

Section 4

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN—INTRODUCTION

Residue testing of animals slaughtered in the United States is divided into three major activities: **monitoring, surveillance, and exploratory projects.**

Monitoring is designed to provide profile information on the occurrence of residue violations in specified animal populations on an annual, national basis. Because the primary concern of monitoring is violations, the compounds considered for monitoring generally have established safe limits--tolerances or action levels. Compounds are selected for monitoring based on risk profiles and the availability of laboratory methodology that is suitable for regulatory purposes. Monitoring information is obtained through a statistically-based selection of random samples from healthy-appearing animals under inspection; area monitoring may be conducted where a localized potential problem appears. The information generated from monitoring is reviewed periodically to assist in the allocation of Agency resources.

In addition to profile information, monitoring provides a basis for further action. In particular, the results are used to identify producers marketing animals with violative concentrations of residues. When such producers subsequently offer animals for slaughter, the animals will be subjected to surveillance sampling and testing until compliance is demonstrated. Other auxiliary uses of the data are to indicate prevalence and concentrations of residues, to evaluate residue trends, and to identify problems within the industry for which educational or other corrective efforts may be needed. Thus monitoring not only gathers information, but also assists in deterring practices that lead to violative residues.

Monitoring samples collected by inspectors at slaughtering plants are sent for analysis either to one of three Food Safety and Inspection Service (FSIS) field laboratories or, as needed, to a laboratory under contract to FSIS. The results are usually reported within eight days after arrival at the laboratory. In most cases, the product will have passed into consumer channels and become untraceable. Because of this pragmatic limitation, some animals containing violative residues inevitably pass into consumer channels, in spite of the agency's efforts to limit this occurrence as much as possible. The consequences to human health, however, are minimal as long as the violative rate is low. Tolerances and action levels represent the maximum residue concentrations safe for daily consumption over a lifetime. Occasional consumption of products with slightly higher residues is unlikely to result in adverse health effects.

Surveillance is designed to investigate and control the movement of potentially adulterated products. The sampling is often purposely biased and is directed at particular carcasses or products in response to information from monitoring or other sources (e.g., industry members or a state agency), or from observations during ante-mortem or post-mortem inspection indicating that adulterating concentrations of residue may be present. In-plant testing procedures may be performed by the inspector, or samples may be submitted to an FSIS laboratory for analysis. Depending upon the weight of evidence that led to the testing, product may be retained until test results indicate the appropriate regulatory disposition. Laboratory testing of surveillance samples is completed as rapidly as possible and takes precedence over monitoring samples.

The 1991 NRP plan estimates the surveillance samples anticipated on the basis of historical data; however, the actual number required depends entirely upon the needs that arise. A major incident, such as the 1979 polychlorinated biphenyls (PCB's) contamination problem, could drastically alter the expected surveillance requirement and may require an adjustment of the monitoring plan.

Exploratory projects are conducted for a variety of reasons, but these activities, whatever their objective, have in common the fact that test results normally are not used to take regulatory action or to trigger follow-up surveillance testing. The design of an exploratory project is not suitable for this purpose.

Exploratory projects generally fall within the following two types:

Studies of the occurrence of residues for which no safe limits (i.e., tolerances or action levels) have been established

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN--INTRODUCTION

There are many chemicals (e.g., trace metals, industrial chemicals, and mycotoxins) that may be inadvertently present in animals yet have no established safe concentrations. Their consistent presence in food (and the resulting need for a tolerance or action level to protect public health) has not been established. FSIS may conduct studies to develop information on the frequency and concentrations at which such residues occur.

These studies may be nationwide or limited to specific geographic areas. Sample collection may be random and statistically based, or biased to obtain "worst case" information. The results are given either to the Food and Drug Administration (FDA) or the Environmental Protection Agency (EPA), which have responsibility for establishing tolerances for contaminants in food under the Federal Food, Drug and Cosmetic Act. Exploratory programs planned on a limited scale may be expanded if preliminary results cause greater concern and make acquiring comprehensive information more urgent.

Other projects as appropriate

These may be designed for various purposes, such as evaluating new methods and approaches to monitoring, or supplementing the information used in considering a compound for monitoring.

Domestic Quality Assurance

The Agency enters into "memorandums of understanding" with segments of the meat and poultry industry to provide assurance that when the animals are presented for slaughter they do not contain violative concentrations of chemical residues. This assurance is based both on reviewing records of critical control points in pre-slaughter management control programs and on residue testing in USDA-accredited laboratories. Because of this control and testing program at critical control points, these animals may be sampled under Quality Assurance sampling rather than under monitoring.

Import Program

Federal meat and poultry inspection laws require foreign countries exporting meat and poultry to the U.S. to impose inspection requirements at least equal to U.S. requirements. As part of the process for a foreign country satisfying the equal-to standard with respect to the U.S., the country must respond to a set of five questionnaires that are designed to obtain information regarding various risk areas. One of these risk areas is residues.

A critical process in the foreign inspection system is residue control and monitoring to ensure that no chemicals or drugs prohibited in animal production in the U.S. are used on animals in foreign countries whose products are destined for the U.S. consumer. Present statutes require that foreign residue control programs include random sampling of animals at slaughter, the use of approved sampling and analytical methods, testing of the target tissue for specific compounds, and testing for compounds identified as potential contaminants of meat and poultry exported to the U.S. In addition, every foreign country must submit annual residue monitoring plans and results of the previous year's testing.

FSIS's International Programs (IP) evaluates foreign residue control programs through the on-site observation of the foreign country's inspection system, including exporting plants, equipment, and laboratories, and through actual sampling of imported product at the time of entry into the U.S. Import reinspection performed by FSIS inspectors located at various ports-of-entry around the country is a check on the effectiveness of foreign inspection systems; a component of the import reinspection process is residue sampling. To ensure that representative samples are selected, a sample is chosen at random from the lot selected for reinspection. The criteria for acceptance or rejection of imported products are the same as those applied to U.S. meat and poultry products prepared under Federal inspection. When test results indicate a violative level of residue in an imported product, every effort is made to locate and destroy any product already in U.S. distribution channels. Subsequent shipments of the same product from the same establishment are retained at the port-of-entry until laboratory results are known. If results are negative, product is permitted to move into commerce; if positive, product is refused entry into the U.S. In addition, all shipments of like product from the country are placed on an increased testing schedule until a record of compliance is re-established.

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN--INTRODUCTION

Annual Plan

The development of the yearly NRP Plan begins in February of the preceding year and progresses by means of discussions, both formal and informal, among the Residue Evaluation and Planning Division of the FSIS Science and Technology Program, other Science and Technology Divisions, other FSIS programs, and involved Federal Agencies; it culminates in formal reviews by FSIS and an interagency working group during the late summer and fall. The plan is based on a "residue/species pair" design concept. The species or production-class groups paired with residues are determined by commonalities in rearing as these factors affect the animal's exposure and the probability that residues may be present at slaughter. For example, market hogs have an exposure-potential profile different from that of boars and sows.

In 1983 FSIS asked the Food and Nutrition Board of the National Research Council (NRC) to evaluate the scientific basis of the present system for inspecting meat and poultry and meat and poultry products and to assess the National Residue Program. The NRC report *Meat and Poultry Inspection: The Scientific Basis of the Nation's Program*, published in 1985, contained a number of recommendations and described the characteristics of an ideal program. During fiscal year 1986, FSIS considered the mission and design of the residue program in terms of the NRC report. This review influenced portions of the 1986 plan and has had an additional impact on the plans from 1987 through 1991.

Although the projections upon which the plan is based are as exact as possible, they may not match budgetary or facility resources, or specific sampling and analytical capabilities or requirements during 1991. Residue control is a dynamic field, with continual change; the plan will be modified during the year as additional information alters the original assessment.

The following describes the tables in which the details of the plan are presented. Preceding the tables is an alphabetical list (with explanatory material) of the compounds included in the 1991 plan.

Table I

Table I lists the residue designations used in the 1991 plan, the compounds included under those designations that can be identified as violative, and the residue codes.

The analytical methods used, the minimal levels of measurement that can be achieved, and references to full descriptions of the methods can be found in the Analytical Capability section of this document. FSIS maintains a laboratory development and quality assurance program to ensure progress in residue testing and the integrity of its test results. Before an analyst is allowed to conduct a test on a monitoring or surveillance sample, he or she must demonstrate adequate proficiency and meet specified standards in analyzing quality-assurance samples. (Additional information on the quality-assurance program can be obtained from the Chemistry Division's Quality Assurance Handbook.)

Whenever possible, multi-residue methods are used to detect the presence of more than one residue in a sample; such procedures are used for chlorinated hydrocarbons, antibiotics, sulfonamides, and other classes of compounds. Some of the multi-residue methods detect the presence of additional compounds not included in this listing; however, the confirmation of identity or precise quantification of these additional residues may not be possible. Some compounds that are not significant public health concerns may be included because they are detected in multi-residue testing procedures. The multi-residue methods and the number of compounds that may be identified by each method are expanded when new or modified technology is available.

Table II

Table II lists the species or production-class groups normally used for a residue/species pair in a statistical design and the apportionment of samples between production classes. Exceptions to the groupings for particular compounds are made when appropriate.

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN--INTRODUCTION

Table III

The number of samples for a given residue/species pair generally is chosen to ensure detection of a problem that affects a specified percentage of the population. Table III shows the relationships among the sample size required to detect a problem, the size of the problem, and the probability of detection.

The number of samples generally is chosen to provide a 95% probability of detecting at least one violation when one percent of the animal population sampled is violative. This requires approximately 300 samples. Ensuring a 95% probability of detecting a problem that affects 0.1 percent of the sampled population would require increasing the number of samples to approximately 3,000. When it is known or anticipated that a residue presents a significant public health problem, sampling may be increased. The increased sampling permits study of trends and geographic or seasonal variation in violation rates, and may aid in preparing effective control actions. Conversely, sample sets of fewer than 300 samples are appropriate when at least one of the following conditions pertains: a minor species is involved; it is known that the prevalence of residues in the species involved is low or apparently nonexistent; slaughter of the species occurs in only a few establishments; cost savings or more urgent demands necessitate the reduction of sampling or laboratory resources.

Collection requests for samples are generated monthly, using an FSIS computerized system in Washington, D.C. Sample and plant selection is random and statistically (probability) based by production class, with a minimal bias. Normally, residues are monitored for the entire year, but some may be introduced during the year and may continue into the following year. Others may be included only during a particular period of the year. Variables such as production volume, geography, and season are addressed statistically within resource constraints. In some cases where method development is incomplete, samples will be collected on a monthly basis but analytical work may be delayed until the methods are implemented.

Table IV

Table IV lists the tissues to be collected for domestic and import sample analysis.

Table V

Table V presents a summary of the combined domestic and import plans. The plans specify the sample units planned for analysis. In the domestic program a livestock sample unit represents one animal. With poultry, a sample unit can be from one animal when the target tissue is a large one such as fat or muscle or the liver in turkeys. In some cases, the target tissue, such as the liver in chicken, is too small to produce an adequate sample. A poultry sample can then be composed by commingling tissues from six birds.

Table VI

In themselves, sample numbers are not good indicators of the actual commitment of resources, or of the effectiveness of these commitments. Table VI illustrates the wide divergence among test procedures in amount of analyst time required per sample.

Table VII

Table VII presents the domestic program sample units planned for 1991, including monitoring, surveillance, and exploratory activities.

Tables VIII-IX

Tables VIII and IX show the monitoring and exploratory sample units planned for domestic livestock and poultry, respectively. The sample unit numbers for each residue designation are presented according to species or production class. The samples to be taken in the voluntary program for rabbits are estimated.

Table X

Table X presents the sample plan for imported products. The design of the import plan differs from the domestic plan because it involves the reinspection of product that has already been inspected under an ap-

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN--INTRODUCTION

proved foreign system with a residue program equal to that of the U.S. Thus port-of-entry residue sampling is intended to provide further information on the operation of the foreign system's residue controls.

The import inspection program uses an Automated Import Information System (AIIS) to direct the selection of samples from any port where product may arrive. Data stored in the AIIS are used for monthly updates of the sampling requirements for each country, product, and residue class, to ensure that the commitments of the annual plan are met. Appropriate changes can be made in the AIIS if, during the course of the year, there are unexpected changes in the volume or type of imported product from any country or countries.

Tables XI-XII

Table XI shows the planned import samples by species and Table XII shows estimated analyses per country.

Tables XIII-XXII

Table XIII shows the estimated annual volume of imported beef, divided into fresh (including frozen) and cured/cooked products. Table XIV lists the sample unit analyses planned for fresh and cooked/cured beef products. Tables XV and XVI follow the same procedure for imported pork; Tables XVII and XVIII for fresh veal, mutton, and lamb; Tables XIX and XX for ducks/geese and turkeys; and Tables XXI and XXII for chickens and goats.

Compounds Included In the 1991 Residue Plan

Antibiotics

During the last decade antibiotic use in food animals, as in human medicine, has been increasingly directed against specific conditions and less toward general therapy or disease prevention. Nevertheless, some antibiotics continue to be fed at subtherapeutic concentrations to enhance feed efficiency and promote growth.

The antibiotics vary widely in their toxicity, safe residue concentrations, and required withdrawal periods. Toxic effects include, for example, life-threatening hypersensitivity responses (penicillins) and hearing impairment (streptomycins). In addition, there is concern about the development and transmission of pathogenic organisms resistant to antibiotic therapy.

The conventional bioassays and ELISA's currently in use by FSIS will identify penicillins, streptomycins, tetracyclines, chloramphenicol, neomycin, erythromycin, gentamicin, and tylosin.

Calves have presented a high percentage of violative antibiotic residues. Until 1988, calves were sampled as a single class. Since 1988 calves tested under surveillance have been divided into four groups: bob (up to 3 weeks of age or 150 pounds in weight); formula-fed calves between 150 and 400 pounds; non-formula calves between 150 and 400 pounds; and heavy calves (over 400 pounds).

Formula-fed calves are a problem because they are slaughtered at three or four months. Consequently, they may retain residues of some long-acting antibiotics in their kidneys or other tissues.

Bob calves present an acute problem, as they are slaughtered before many drugs that might be administered can deplete to safe concentrations. FSIS conducts an intensive in-plant testing program --the Calf Antibiotic and Sulfonamide Test (CAST) program--directed at violative antibiotic and sulfonamide residues in bob calves.

Cows presented for slaughter are usually culled from beef or dairy herds for substandard performance and may have been treated before slaughter. Consequently, cows also have had a relatively high percentage of violative residues. Since cows are often presented for slaughter singly or in small lots, it has proved difficult to trace violative carcasses found in monitoring to their place of origin for follow-up surveillance testing. FSIS

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN--INTRODUCTION

has an in-plant testing program for cows suspected of containing violative residues--the Swab Test on Premises (STOP) program--that has been effective over the years in reducing the previously very high violation rate in this vulnerable group of animals. All cows sampled under the national monitoring program will be concurrently screened by the STOP test. Carcasses that are STOP-positive will be retained pending confirmation of adulteration by laboratory analysis. Before 1989 both beef and dairy cows were grouped together with bulls as a single production class; since 1990 dairy cows have been sampled separately from beef cows. All fresh imported product will be sampled and tested for antibiotics in 1991.

Sulfonamides

Sulfonamides are bacterial and protozoal suppressant drugs that have been widely used in animals and humans since the early 1940's. They continue to be popular because of their economic advantages and wide spectrum of activity. Toxic effects include renal damage, thyroid degeneration, and allergy. Sulfonamides that can be determined as violative include sulfachlorpyridazine, sulfadimethoxine, sulfaethoxypyridazine, sulfamethazine, and sulfathiazole. Sulfadiazine, sulfadoxine, sulfamethoxypyridazine, sulfaphenazole, sulfaipyridine, sulfaquinoxaline, sulfatroxazole, and sulfisoxazole are also detectable.

Domestic monitoring samples are planned for 1991 in all species/production groups. Monitoring samples from market hogs will be continued at 3,600 so as to provide monthly estimates of the frequency of violative concentrations. In the import plan, all commodities will be sampled for sulfonamide testing.

Arsenic

Organic arsenical compounds, either alone or combined with other compounds, have been widely used both in humans and in food-producing animals as tonics, restoratives, herbicides, pesticides, protozoal and helminthologic agents, antimicrobials, and growth promoters. They are approved for use in poultry as growth promoters and, in conjunction with other compounds, as coccidiostats; they are used in swine as growth promoters and to prevent bacterial enteritis.

When arsenicals are used as approved in chickens and swine, the animals or birds must not be treated with or exposed to the arsenical compounds within five days of slaughter. This five-day withdrawal period is sufficient to ensure that concentrations of arsenic in the tissues are lower than the tolerance concentrations.

Inorganic arsenicals have been linked to skin, lung, and liver cancer. The organic arsenical compounds used in food animal production do not seem to have carcinogenic or irritant effects.

Arsenic is included in the domestic monitoring plan for horses, cows, goats, market hogs, and young chickens and turkeys. The imported products to be tested for the presence of arsenic include fresh and processed pork, goats, fresh turkeys and chickens and processed turkey and chicken products.

Benzimidazoles

The five benzimidazoles detected by FSIS's current method that can be confirmed as violative are albendazole, benomyl, fenbendazole, oxfendazole, and thiabendazole and its metabolite. These compounds are variously used as pesticides, and as anthelmintics in several species for treatment of gastrointestinal or lung worms.

Undesirable side effects frequently encountered in human beings treated with benzimidazoles are anorexia, nausea, vomiting, and dizziness. Less frequently noticed are diarrhea, epigastric distress, drowsiness, and headache.

In 1991 cattle, sheep, lambs, goats, market hogs, and young chickens will be tested for benzimidazoles. Imported beef, veal, pork, mutton and lamb, goats, and chicken will also be sampled and tested for these compounds.

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN--INTRODUCTION

Carbadox

Carbadox is approved for use in swine weighing less than 75 pounds to prevent or treat enteritis and for increased feed efficiency and weight gain. The last exposure of swine to carbadox must be at least 10 weeks before slaughter. The parent compound is a liver carcinogen. In 1991 domestic market hogs, boars, and sows will be monitored, and surveillance sample unit analyses are projected to test for the presence of carbadox in roaster pigs. As carbadox is approved in other countries for use with swine, it is included in the import plan for pork.

Carbamates

Carbamates are primarily systemic insecticides and acaricides but are also used extensively as soil treatments and as topical and knockdown agents for ectoparasites and other pests. Carbamates are cholinesterase inhibitors and are generally neurotoxic. Symptoms of toxicity include nausea, vomiting, diarrhea, and dyspnea.

Analysis for carbamates includes aldicarb and its two metabolites, carbaryl, and carbofuran and its metabolite 3-hydroxycarbofuran. During 1991, 1,300 domestic monitoring samples from dairy cows, veal calves, and ducks will be analyzed for these carbamates; in the import plan, beef and veal will be sampled. An exploratory project in several classes of animals will include bendiocarb, bufencarb, 3,5-Dimethyl-4-(methylthio)phenyl methylcarbamate and its metabolite 3,5-Dimethyl-4-(methylsulfinyl)phenyl methylcarbamate, dioxacarb, isoprocarb, methomyl, oxamyl, promacarb, and propoxur.

Chlorinated Herbicides

This group of compounds, many of which are used extensively, are selective herbicides, insecticides, and preservatives. Many of these compounds have been cancelled or restricted due to concern regarding mutagenicity, carcinogenicity, and teratogenicity. For example, pentachlorophenol (PCP) has been used in the past as a wood preservative, herbicide, and insecticide; currently, only wood preservative uses are permitted. The use of PCP in wood manufacturing is declining; however, wood shavings and sawdust from PCP-treated boards may be used inadvertently as animal bedding.

The method, developed by Hopper, identifies bromoxynil, 2,4-D, dicamba, PCP, silvex, and triclopyr. Results from the screen will be reported as exploratory data.

Chlorinated Hydrocarbons and Organophosphates (CHC/COP's)

FSIS laboratories use multi-residue and confirmatory analytical procedures that can identify aldrin, BHC, captan, chlordane, DDT and metabolites, dieldrin, dodecachlorooctahydro-1,3,4-metheno-2H-cyclobuta[cd]pentalene [mirex], toxaphene, endosulfan, endrin, heptachlor and heptachlor epoxide, HCB, lindane, linuron, methoxychlor, PCB's, and terpene polychlorinates. In 1987 the chlorinated hydrocarbon method was modified slightly to include residues in fat from a group of chlorinated organophosphates. The domestic samples tested for chlorinated hydrocarbons yield results for seven chlorinated organophosphates: carbophenothion, 2-chloro-1-(2,4-dichlorophenyl)vinyl diethyl phosphate [chlorfenvinphos], 2-chloro-1-(2,4,5-trichlorophenyl)vinyl dimethyl phosphate [stirofos], chlorpyrifos, coumaphos, phosalone, and ronnel.

Most of these compounds are potent and persistent pesticides the use of which has been discontinued or severely restricted because of concerns regarding mutagenicity, carcinogenicity, hazard to wildlife, and bioaccumulation. Accumulation of chlorinated hydrocarbons in body fat may result in concentrations 10 to 30 times as great as in the food supply. Metabolism and excretion are slow, and the biological half-life of these compounds may be several months in mammals and several years in arid soils. Their persistence and potency make them effective long-term pesticides but also cause their continuing though diminishing occurrence as residues in meat and poultry products. Many uses are currently cancelled or restricted.

During 1991 analyses are planned for all domestic and imported species and production classes.

1991 NATIONAL RESIDUE PROGRAM (NRP) PLAN—INTRODUCTION

DES

Diethylstilbestrol (DES) is an estrogenic compound once approved for use to increase feed efficiency and the rate of weight gain. DES was banned from use in 1979 when it was linked to cancer in humans. Some illegal use was detected in fancy veal calves in 1981. Domestic monitoring activities for DES include 300 samples from domestic heifers and steers. Imported fresh beef will be sampled for DES.

Halofuginone

Halofuginone is a coccidiostat for young chickens and young turkeys. In higher doses halofuginone is a growth depressant, impairs feed utilization, and reduces feed intake. In rats it causes alopecia. The compound is prohibited from use during the last four days before slaughter. Domestic and imported young chickens and turkeys will be monitored for halofuginone in 1991.

Ivermectin

Ivermectin is a macrocyclic lactose compound active at extremely low doses against a wide variety of nematode and arthropod parasites. Ivermectin is teratogenic in the rat, rabbit, and mouse. Most domestic and imported livestock species will be monitored for ivermectin.

Nicarbazin

Nicarbazin is a coccidiostat used in young and mature chickens. In 1991, 600 domestic samples will be tested for nicarbazin.

Nitroimidazoles

A nitroimidazole (ipronidazole) was previously approved for domestic use to control blackhead in turkeys and in other countries to treat or prevent enteritis in swine. It is a suspect carcinogen in experimental animals.

In 1991 samples for the nitroimidazoles (ipronidazole and dimetridazole) will be collected from imported pork and turkeys, and domestic young turkeys.

Pyrethrins/pyrethroids

Pyrethrins are a group of natural insecticides obtained chiefly from the flowers of *Crysanthemum cinerariaefolium*. These compounds are used widely because their mammalian toxicity is low relative to their insecticidal properties. Pyrethroids, for example, permethrin, are synthetic compounds that mimic the biological activities of the natural pyrethrins.

The 1991 domestic monitoring program will include sampling of dairy cows and formula-fed calves for cyano (3-phenoxyphenyl) methyl-4-chloro-a-(methylethyl) benzeneacetate, cypermethrin, flucythrinate, and permethrin.

TABLE I: Compounds in 1991 Residue Plan

Residue Designation	Compounds	Residue Code
ANTIBIOTICS	Chlortetracycline Erythromycin Gentamicin Neomycin Oxytetracycline Penicillins Streptomycin Tetracycline Tylosin	209 206 211 207 208 201 202 204 205
